

Project Report

The objective of this project is to develop a web application that classifies an uploaded image as either a cat or a dog using a MobileNet deep learning model. The application is deployed using the Flask framework and displays the predicted class along with the confidence score.

- A pretrained MobileNet model is trained using a cat and dog image dataset. The trained model is saved as cat-dog-classify.keras. A Flask web application is created to allow users to upload an image. The uploaded image is resized to 160×160 pixels, converted into an array, and passed to the trained model for prediction. The application then displays the uploaded image, the predicted class (cat or dog), and the confidence percentage through a modern web interface.

The project successfully demonstrates the use of Deep learning and Flask to build an image classification web application.
